

THE COMPLEX PARAMETERS THAT ARE USED FOR ROUTING RESULTS ASSESSMENT AND COMPARISON

Parameter	Parameter explanation	Expected result		
Number of assigned activities	The value of assigned activities defines the profit	Should be maximized by routing		Assessment of profit
Price of losses (costs)	Sum of losses gained because of travel, overdue, SLA violation	Should be minimized by routing		
Rout density parameter	Defines the efficiency of workforce usage	If all activities are assigned it should be minimized otherwise maximized		Assessment of efficiency
Value of overtime	The losses that associated with the extra time of work for each tech.	Shod be minimized by routing		

TECHNICAL DESIGN

Input parameters from the rhs server

Assessment of profit and loss that was obtained by the routing is based on the parameters of penalty prices of overdue, travel and SLA violation.

AA - Assigned Activities

$$AA = \text{raw_total_activities} - \text{raw_not_assigned_activities}$$

OvC – Overdue cost

TrC – Travel cost

SIC – Sla violation cost

$$OvC = \frac{\text{sum_overdue_time}}{AA}$$

$$TrC = \frac{\text{sum_travel_time}}{AA}$$

$$SIC = \frac{\text{sum_sla_violation}}{AA}$$

RP - Average profit on each assigned job

$$RP = \frac{\text{info_sum_assigned}}{AA}$$

Target vector*

<i>OvC</i>	<i>TrC</i>	<i>SIC</i>	<i>RP</i>
<i>0</i>	<i>0</i>	<i>0</i>	<i>1</i>

*0 – decreasing is preferable

*1 – increasing is preferable

Normalized Target parameters

AAs – percentage of assigned activities

$$AAs = \frac{AA}{\text{raw_total_activities}}$$

AL* - Average loss on each assigned job

$$AL = \frac{\text{sum_overdue_time} + \text{sum_travel_time} + \text{sum_sla_violation}}{AA}$$

Complex target vector

AAs	AL
<i>1</i>	<i>0</i>

0 – decreasing is preferable
1 – increasing is preferable

*In order the parameter **info_sum_assigned** is not available for all the routing versions, the relative assessment of losses is calculated by dividing the maximum value of losses(AL) from the all compared results.

Assessment of efficiency

The **complex assessment of effective time** is formed with the indexes represented below.

WT – work time

$$WT = \text{raw_work_time_sum} + \text{raw_travel_time_sum} + \text{raw_waiting_time_sum}$$

RD – rout density

$$RD = \frac{\text{raw_work_time_sum}}{WT}$$

Ov – overtime

$$Ov = \frac{\text{raw_overtime_soft_sum} + \text{raw_overtime_hard_sum}}{\text{providers_used}}$$

OvWt – percentage of overtime in the Work time

$$OvWt = \frac{Ov}{WT}$$

Complex target vector*

RD	OvWt
1	0

Summary assessment

Summary target vector

According to the essential meaning of the rout density parameter and its level of significance the target parameter of this value depends on the percentage of assigned activities, so the target vector has two different options:

1. All activities are assigned (AAs==1)

AAs	AL	RD	OvWt
1	0	0	0

2. Not all activities are assigned (AAs!=1)

Tvector:

AAs	AL	RD	OVWt
1	0	1	0

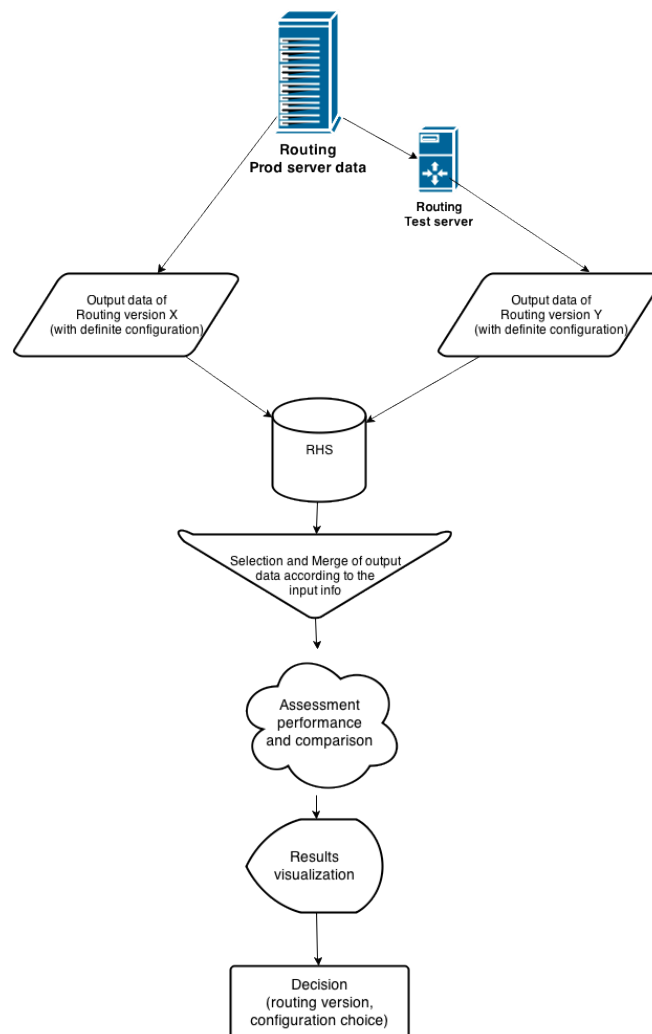

The **summary assessment** is calculated using the value of correlation between the calculated and target vectors. the Pearson product-moment correlation coefficient between the **Tvector** and **N_rout**(constructed with the routing results);

$$r = \frac{\sum(N_rout - E(N_rout))(Tvector - E(Tvector))}{\sigma_{N_rout}\sigma_{Tvector}}$$

The value r is calculated for every routing result and the comparison of these values is performed for the similar routing run id. The higher it is for the specific case the better quality of rout can be registered. The most probable value of this r value is used further.

Now the comparison is developed using the Rstudio environment and results of assessment for all the companies are calculated.
